# New Keynesian Phillips Curve is still alive Interpretation of low inflation episode in Poland

Tomasz Łyziak<sup>†</sup>

#### Abstract

Deflation in Poland, similarly as low inflation in the advanced economies, particularly in the euro area, seems surprisingly and unexpectedly persistent. This paper attempts to verify to what extent traditional and hybrid versions of the New Keynesian Phillips Curve (HNKPC) are useful in analysing recent inflation developments in Poland. To make our analysis comprehensive and the conclusions robust, estimating the New Keynesian Phillips curves we take into account different variables representing inflation, inflation expectations, economic slack and imported inflation.

Our results suggest that the recent disinflation in Poland – that started in 2012 and have resulted in a prolonged deflation period – has been driven not only by a fall in commodity prices, but also by demand factors and by a reduced level of inflation expectations. We show that in order to make the HNKPC models able to replicate the recent disinflation, a specific set of proxies for explanatory variables should be used. It should include survey-based measures of economic agents' inflation expectations (particularly, inflation expectations of enterprises), the transformed measure of the output gap that allows for a stronger impact of economic activity on inflation when the output gap is high or GDP growth rate relative to its mean as well as the real exchange rate gap.

Analysing stability of the Phillips curve estimated in terms of core inflation we find some signs of its flattening in recent years. At the same time HNKPC models with CPI inflation as explanatory variable suggest rather a steepening of the Phillips curve. Both types of models indicate, however, that the link between inflation expectations and actual inflation has been weakened recently.

#### 1. Introduction

Before the collapse of the Lehman Brothers, many advanced and emerging economies experienced a prolonged period of low and stable inflation. Reduction of the level and volatility of inflation was perceived as the sign of success of central banks, whose credibility contributed significantly to the Great Moderation period. Since the beginning of the Great Recession inflation has become more volatile and its path in advanced economies has displayed a twin puzzle (Constâncio, 2015), i.e. first, a missing disinflation in 2009-2011, and second, excessive disinflation after 2012, particularly in Europe (Figure 1). Even if inflation during both these episodes was driven by changes in commodity prices, its level seems not fully consistent with developments in the real economy, i.e. with negative growth rates of the real GDP in the U.S. and the euro area after the beginning of the sharp phase of the financial crisis and more recently – with a gradual economic expansion. A twin puzzle has provoked numerous analyses aimed at assessing to what extent observed inflation developments are consistent with existing models of inflation, particularly with those based on the Phillips curve specifications.

#### [Figure 1 here]

Inflation in Poland has followed similar developments as in the advanced economies in recent years (Figure 1, Figure 2). Affected by high energy and food prices it significantly exceeded the inflation target of the National Bank of Poland (2.5% with a range of tolerable deviations  $\pm 1$  pp.) in the aftermath of the financial crisis (years 2008-2009 and 2010-2012). Then, in 2014-2015 a very fast disinflation was taking place – CPI inflation was reduced from 4.6% in 2011Q4 to -1.5% in 2015Q1. Since then it has remained in the negative territory till now (2016Q2). It should be noted that the depth of disinflation in Poland has been bigger than in the U.S. and the euro area. It is probably mainly due to a different composition of consumer baskets – the share of foodstuffs and energy in Poland is significantly bigger than in the U.S. and in the euro area (Table 1).

#### [Table 1 here]

The deflation in Poland has been broad-based – at its early stage, in late 2014, the weight of CPI basket components, whose prices displayed reductions on annual basis was approaching as much as 45% (NBP, 2014, p. 22). Moreover, not only CPI inflation was subject to significant reductions, but also core inflation measures. Since 2014 the latter ones either have been negative (inflation net of administrative prices) or have oscillated around the levels close to zero (inflation net of the most volatile prices, inflation net of food and energy prices and 15% trimmed mean).

# [Figure 2 here]

Two aspects of Polish disinflation should be underlined. First, both the magnitude of disinflation and the persistence of negative inflation rates were expected neither by professional forecasters (see Figure 3), nor by monetary authorities.<sup>1</sup> Second, in contradiction to the most common explanation of low inflation in Poland, treating it as a global phenomenon, resulting mainly from a sharp fall in commodity prices in the global markets, very low levels of core inflation measures indicate that the reasons of deflation are more complex.

#### [Figure 3 here]

The above circumstances lead to the question whether the period of low and negative inflation in Poland should be considered puzzling from the point of view of our understanding of the nature of

<sup>&</sup>lt;sup>1</sup> See macroeconomic projections presented in NBP Inflation Reports.

inflation processes in Poland. To what extent the Phillips curve models are alive, being able not only to describe recent inflation performance, but also to forecast inflation in advance? What are determinants of deflation in Poland?

The present study aims at answering the above questions. Referring to selected studies that analyse inflation puzzles in the U.S. and euro area economies we perform similar analysis using Polish data. The main focus is to verify if the recent disinflation can be explained *ex post* and if it could have been predicted *ex ante* with the use of the hybrid New Keynesian Phillips curve. Estimating it we use different measures of the economic slack and inflation expectations, trying to find the most accurate specification. In addition, we analyse changes in the estimation results of the Phillips curve during the recent disinflation in Poland.

The second section provides a brief review of the literature, focusing on selected studies being the most relevant for our analysis. The third section discusses methods and data used in the empirical part of the paper. The fourth section presents the results. The final section concludes the study.

#### 2. Literature review

The Phillips curve can be broadly described as the relationship between inflation and economic slack, extended with additional factors affecting price changes. In the New Keynesian framework they include in particular inflation expectations. Such a relationship is known as the New Keynesian Phillips Curve, NKPC (Goodfriend and King, 1997). It assumes that in every period only a fraction of prices  $(1-\alpha, 0 < \alpha < 1)$  are adjusted, while the remaining ones  $(\alpha)$  stay unchanged. As a result, the current inflation rate  $(\pi_t)$  is a function of currently expected price changes  $(E_t \pi_{t+1})$ , treated usually as rational, and of cyclical component of economic activity  $(\hat{y}_t)$ , i.e. the deviation of output or real marginal costs from their trends<sup>2</sup>:

$$\pi_t = \beta E_t \pi_{t+1} + \kappa \hat{y}_t + \varepsilon_t \tag{1}$$

In the case of open economies the above relationship is extended and includes in addition terms of trade, real exchange rate or import prices (e.g. Galí and Monacelli, 2005; Abbas *et al.*, 2016).

From the empirical point of view there were some doubts concerning the NKPC emerging. Such a relationship neither explains the phenomenon of persistently high inflation nor predicts costs of disinflation that in real economy seem substantial (e.g. Ball, 1993; Fuhrer and Moore, 1995). This empirical inconsistency led to an alternative specification of the above relationship, i.e. to the Hybrid New Keynesian Phillips Curve, HNKPC, in which explanatory variables contain lagged inflation in addition:

$$\pi_t = \omega E_t \pi_{t+1} + (1-\omega)\pi_{t-1} + \kappa \hat{y}_t + \varepsilon_t \tag{2}$$

 $<sup>^2</sup>$  In the original version of the NKPC the real marginal cost is the measure of economic slack. Under particular assumptions real marginal costs can be substituted with the output gap (Rotemberg and Woodford, 1999; Sbordone, 2002). In empirical applications there are however different variables that proxy the excess demand in the economy.

The role of lagged inflation is motivated in various ways. It can result from the wage contracting model (Fuhrer and Moore, 1995), in which agents aim at maintaining a given level of the real wage during the time of the contract. It can also reflect heterogeneity of economic agents and the hybrid model of formation of their expectations (Lovell, 1986; Roberts, 1997; Galí and Gertler, 1999). In this case parameter  $\omega$  can be interpreted as the share of economic agents whose expectations are consistent with the unbiasedness property of the rational expectations hypothesis, while the remaining share of agents,  $1 - \omega$ , form expectations in the backward-looking (static) manner. Finally, lagged inflation in the HNKPC can be independent of the heterogeneity of expectations' formation, reflecting rather indexation of wages and prices (Christiano *et al.*, 2005)

Both versions of the New Keynesian Phillips Curve have become the workhorses of empirical modelling of inflation. They have also provoked intense academic debates. It is not the aim of this paper to provide the overview of this discussion, especially given that comprehensive literature reviews exist (e.g. Nason and Smith, 2008; Mavroeidis *et al.*, 2014; Abbas *et al.*, 2016). Instead in this section we are going to present the studies that constitute the most important benchmarks for our analysis. However, it should be underlined that a large part of the debate concerning the NKPC has been focused on the ways of measuring key variables included in this relationship, especially the real marginal costs and inflation expectations. Being aware of pros and cons of different choices in this respect, in this paper we apply the agnostic approach, estimating the NKPC with the use of different measures of excess demand and inflation expectations. In the area of measuring inflation expectations we relax the assumption of rational expectations and make use of survey measures of inflation expectations. Although this approach is not micro-founded, it has been applied successfully in many empirical studies (e.g. Henzel and Wollmershäuser, 2006; Paloviita, 2008; Forsells and Kenny, 2010).

As mentioned in the Introduction, price developments after the collapse of the Lehman Brothers have displayed two puzzles that are analysed in empirical literature. The first one is the missing disinflation puzzle in 2009-2011. Despite large increases in unemployment during the Great Recession, inflation in advanced economies did not fall as much as past experiences would have predicted. This puzzle in part can be caused by the flattening of the Phillips curve – the phenomenon resulting both from the globalization, i.e. increased role of foreign output gap and decreased role of domestic output gap in influencing prices (Borio and Filardo, 2007), as well as from a more credible monetary policy, leading to more firmly anchored inflation expectations (Bernanke, 2010; Kuttner and Robinson, 2010). There are also other explanations of the missing disinflation puzzle, including the observation that the rise in unemployment during the Great Recession was structural, i.e. it translated to wages and prices less than in the past (IMF, 2013) and the findings of increased downward wage rigidities in the recession (Daly and Hobijn, 2014).

It is worth focusing attention on one of the studies analyzing in detail the missing disinflation in the U.S. economy, i.e. on the influential article by Coibion and Gorodnichenko (2015) that noticeably inspired the research presented in this paper. The authors analyse the phenomenon of missing disinflation in 2009-2011 with the use of expectations-augmented Phillips curve. They show that none of the traditional explanations appear sufficient to describe inflation developments during the Great Recession. The anchored expectations hypothesis (Bernanke, 2010) can explain only a part of the missing disinflation. Explanations based on the labour market performance mentioned above imply that the missing disinflation in prices should have been accompanied by the missing disinflation in wages, which is not confirmed by the data. Also the effects of the flattening of the Phillips curve seem insufficient to explain much of the missing disinflation. Instead of concluding that from this perspective the Phillips curve is useless in explain inflation performance during the period under consideration, Coibion and Gorodnichenko (2015) propose another explanation. They show that the

expectations-augmented Phillips curve, in which Michigan survey measures of households' inflation expectations are used, can account for the absence of strong disinflationary pressures in 2009-2011. It is due to the fact that in contradiction to inflation forecasts of professional forecasters, whose expectations were relatively stable, household inflation expectations experienced a sharp rise, going from 2.5% in 2009 to 4% in 2013. This increase was caused by developments in oil prices, rising sharply since 2009. This explanation, quantitatively the most successful in capturing the absence of disinflation within the Phillips curve framework, goes in the opposite direction to Bernanke's anchored expectations, treated as the adequate proxy for firms' inflation expectations, prevented the U.S. economy from deflation.<sup>3</sup> The authors conclude that while anchored inflation expectations remain desirable in most circumstances, the experience since 2009 presents a cautionary example of the potential downside of fully anchored expectations.

The second study that influenced the direction of research presented in this paper is the analysis by Constâncio (2015), based on the results of the ESCB Low Inflation Task Force.<sup>4</sup> It aims at explaining excessive disinflation puzzle in the euro area economy after 2012. Even if low inflation rates in recent years can be driven by a decline in the oil prices, it is not the complete explanation given that core inflation measures have also been below average in the euro area and in other developed economies. A part of research is based on the hybrid New Keynesian Phillips Curve, estimated with different proxies for the economic slack and inflation expectations. Constâncio (2015) shows that several specifications of the HNKPC are able to track recent disinflation. These models tend to be those that use the unemployment rate or unemployment gap and short- to medium-term measures of inflation expectations. In addition the study discusses stability of the Phillips curve, supporting evidence on the steepening of the Phillips curve in recent years.<sup>5</sup> This effect seems especially marked in the economies that experienced deeper and longer recessions and made greater efforts to reform their product and labour markets, with an impact on nominal rigidities. The natural question that arises in this respect is to what extent the steepening of the Phillips curve can signal inflation expectations becoming unanchored. Empirical studies indicate subtle signs of de-anchoring of inflation expectations in the euro area (e.g. Łyziak and Paloviita, 2016).

However, there are other explanations of the recent steepening of the Phillips curve in the euro area. Riggi and Venditti (2015) claim that it can result either from lower nominal rigidities due to structural reforms in stressed countries or from a decrease in strategic complementarities in price setting, related to a fall in the number of firms in the economy after the Great Recession. Another possibility taken into account is the increase of the frequency of price adjustments, but empirical studies on this issue has provided mixed results so far.

This study aims at contributing to empirical literature using the Phillips curve to explain price developments in the Polish economy. Kokoszczyński *et al.* (2010) show that survey-based measures of consumer inflation expectations are useful in estimating the hybrid New Keynesian Phillips Curve in Poland and in the Czech Republic. However, according to their estimates, the backward-looking

<sup>&</sup>lt;sup>3</sup> This assumption seems debatable. Bryan *et al.* (2015) indicate that US firms' inflation expectations are very similar to the predictions of professional forecasters, despite a somewhat greater heterogeneity of expectations. Similar conclusions apply also in the case of Poland (e.g. Łyziak, 2013).

<sup>&</sup>lt;sup>4</sup> The results collected by the Low Inflation Task Force will be presented in detail in the report forthcoming in the ECB Occasional Papers.

<sup>&</sup>lt;sup>5</sup> Oinonen and Paloviita (2014) estimate time-varying parameters for the hybrid New Keynesian Phillips Curve In the euro area, using different proxies for the output gap. They show that the slope of the Phillips curve has become steeper after 2012.

component in this relationship is stronger than the forward-looking one, independently of the measure of inflation expectations used. Hałka and Kotłowski (2014) estimate the Phillips curves in the disaggregated manner, i.e. for individual price indexes. They find that more than 55% of the categories react to the output gap (mainly services and nondurable goods), while more than one-third of prices respond to exchange rate movements (mainly durable and semi-durable goods). At the same time globalization process makes only a small share of prices of durable and semi-durable goods react to domestic demand.<sup>6</sup> Even if the specification of the Phillips curves used by Hałka and Kotłowski (2014) does not include forward-looking elements, the results of their analysis suggest that the concept of the open-economy NKPC can be useful in analysing price developments in Poland. Łyziak (2016) uses rational expectations and survey-based measures of inflation expectations of various groups of economic agents in estimating the small stylized New Keynesian model of monetary policy with Polish data. Estimation results show that with survey-based measures the expectation term in the NKPC becomes significantly larger than in the model with rational expectations, although in all the cases the role of lagged inflation is somewhat stronger than the role of expected inflation. Surveybased measures of inflation expectations of Polish consumers, financial sector analysts and, particularly, enterprises, contain forward-looking information that improves forecasting properties of the New Keynesian model relative to its type with rational (model-consistent) expectations. Inflation expectations of enterprises seem the most powerful in this respect.

#### 3. Methods and data

Before analyzing recent inflationary developments in Poland with the use of the New Keynesian Phillips Curve we consider the drivers of deflationary episodes in different economies to answer the question whether the Polish deflation is surprising taking them into account. In this respect we use the Deflation Vulnerability Index (DVI) proposed by Kumar et al. (2003), that combines determinants found to lead deflationary episodes in different economies. The index reflects developments in aggregate prices, economic activity, asset markets, and credit and financial markets. In the above groups there are 11 specific indices considered, each of them of binary nature, with a value 1 reflecting possible deflationary pressure from a given source and otherwise the value of zero. Subsequent components of the index equal 1 if: (1) annual inflation, measured as a change in the CPI, is less than 0.5%; (2) annual inflation, measured as a change in the GDP deflator, is less than 0.5%; (3) annual inflation, measured as a change in the core CPI, is less than 0.5%; (4) the output gap has widened by more than 2 percentage points over the last 4 quarters; (5) the output gap is less than -2%; (6) the real GDP growth over the last 3 years is less than annual average growth over the preceding decade; (7) the broad measure of the stock market over the last 3 years has fallen by more than 30%; (8) the real effective exchange rate has appreciated by more than 4% over the last 4 quarters; (9) the private, nominal credit growth is less than nominal GDP growth over the last 4 quarters; (10) the cumulative private, nominal credit growth over the past 3 years is less than 10%; (11) the broad money (M3) growth on a y/y basis has grown slower than base money by 2 percentage points (or less) over the last 8 quarters.

<sup>&</sup>lt;sup>6</sup> In their recent paper Hałka and Kotłowski (2016) deepen the analysis of the global determinants of domestic inflation in Sweden, Poland and Czech Republic. They find that the low inflation in those countries results not only from favourable shock to commodity prices, but is also due to weak demand, both internal and external. Moreover, they show that since the beginning of financial crisis the role of demand shocks affecting inflation was more important than the role of supply shocks.

Estimating the hybrid New Keynesian Phillips curve models for Poland we take into consideration different variables that proxy inflation developments, inflation expectations, economic slack and imported inflation. According to the notation applied, the model  $i_k_m_h$  denotes the HNKPC specification, in which we use the *i*-th measure of inflation as the dependent variable and among explanatory variables there are: the *k*-th measure of the economic slack, the *m*-th measure of inflation expectations and the *h*-th measure of imported inflation.

We use two measures of consumer price changes in Poland  $(\pi^{(i)})$ , i.e. the annualized rate of growth of the overall Consumer Price Index, CPI (i = 1) or annualized the core inflation that excludes foodstuffs and energy items (i = 2).

There are six measures of the economic slack  $(y^{(k)})$  considered in this study. The first one is given by the output gap estimated with the use of the Hodrick-Prescott (HP) filter (k = 1). The second measure of the economic slack (k = 2) is a transformed version of the HP-filter output gap, capturing potential non-linear effects of the excess demand on inflation in the periods, when the output gap is positive. This transformation, proposed by Alichi *et al.* (2009), has the following form:

$$\hat{y}_{t}^{(2)} = \begin{cases} \frac{\hat{y}^{max}}{\hat{y}^{max} - \hat{y}_{t}^{(1)}} \cdot \hat{y}_{t}^{(1)} & for \ \hat{y}_{t}^{(1)} > 0\\ \hat{y}_{t}^{(1)} & for \ \hat{y}_{t}^{(1)} \le 0 \end{cases}$$
(3)

The remaining measures of the economic slack comprise the output gap obtained with Christiano-Fitzgerald (CF) filter (k = 3), asymmetric CF-filter output gap transformed in the way proposed by Alichi *et al.* (2009) (k = 4), a deviation of the real GDP growth rate from its mean (k = 5) and the inverse of the unemployment rate gap, estimated with the HP filter (k = 6).<sup>7</sup>

Inflation expectations  $(\pi^{e(m)})$  are proxied with the following measures: cumulative mean of CPI inflation (m = 1), NBP inflation target (m = 2) as well as with survey-based measures of short-term (12 months ahead) inflation expectations of enterprises (m = 3), financial sector analysts (m = 4) and consumers (m = 5).<sup>8</sup>

Finally we use two proxies reflecting imported inflation  $(\pi^{f(h)})$ , i.e. annualized growth rate of import prices (h = 1) and the real effective exchange rate gap, calculated with the HP filter (h = 2).

The general form of the estimated hybrid version of the NKPC in the case of the model  $i_k_m_h$  is the following:

$$\pi_t^{(i)} = c_1 \pi_{t-1}^{(i)} + c_2 \pi_t^{e(m)} + c_3 \hat{y}_{t-l^y}^{(k)} + c_4 \pi_{t-l^f}^{f(h)} + \varepsilon_t$$
(4)

where the lags of the output gap  $(l^y)$  and of the foreign component  $(l^f)$  are selected on the basis of statistical fit (in the estimated equations they equal 0 or 1).

<sup>&</sup>lt;sup>7</sup> In the cases of both measures of the output gap based on Alichi *et al.* (2009) concept, different values of  $\hat{y}^{max}$  were tested. Finally, the best statistical fit of HNKPC models was obtained for  $\hat{y}^{max}$  equal 0.05.

<sup>&</sup>lt;sup>8</sup> Survey-based measures of inflation expectations are the same as used in Lyziak (2016).

We estimate the Phillips curves using two sample periods. Both of them start in 2003Q1, while they end either in 2015Q3 (full sample period) or in 2011Q4, i.e. before the recent disinflation started (short sample period). Checking stability of the Phillips curve during the period of recent disinflation we compare the estimated short-run coefficients as well as the long-run impact of inflation expectations, economic slack and foreign prices on domestic inflation, given by the respective coefficients:  $\frac{c_2}{1-c_1}$ ,  $\frac{c_3}{1-c_1}$  and  $\frac{c_4}{1-c_1}$ .

Estimating the equations we do not impose dynamic homogeneity – the property that makes the Phillips curve vertical in the long run. This condition is, however, verified empirically with the Wald test. If the openness of the economy is represented by the real exchange rate gap, the dynamic homogeneity property is given by the condition:  $c_1 + c_2 = 1$ , while in the case of using annualized rate of growth of import prices – by the condition:  $c_1 + c_2 + c_4 = 1$ .

The HNKPC models contain unobservable variables – inflation expectations and economic slack – that can be subject to measurement errors. In such circumstances the overall error of the equation becomes a combination of an exogenous shock and the measurement error of explanatory variables. For this reason we estimate Phillips curves using the Generalized Method of Moments (GMM). We use lagged values of explanatory variables as instruments, which seems a common choice in the literature (Nason and Smith, 2008).

### 4. Results

Recent disinflation and ongoing deflation in Poland were largely unexpected and are perceived mainly as the result of a fall in commodity prices. The Deflation Vulnerability Index (DVI) introduced by Kumar *et al.* (2003) and used by IMF in assessing deflationary risks in different economies<sup>9</sup>, allows analysing a range of potential causes of deflation, in particular the demand factors.

Figure 4 presents DVI calculated for Poland compared with CPI inflation. Both series are fairly correlated with each other – the Pearson correlation coefficient equals -0.65, while the Spearman rank correlation coefficient approaches -0.54.<sup>10</sup> It seems therefore that the index contains some information about price developments. Analysing its sub-components we can observe that recently deflationary risks have been caused not by a single factor, i.e. positive supply shock exerting downward pressure on prices, but also by other factors, i.e. by developments in the real economy and in credit and money aggregates. During the latest disinflation that started in 2012 Deflation Vulnerability Index increased considerably and recently it has been close to 0.5, signalling – according to classification introduced by Kumar *et al.* (2003) – moderate or almost high deflationary risks.<sup>11</sup>

#### [Figure 4 here]

Given its high correlation with actual inflation it seems that DVI can be a useful tool in analysing inflation perspectives in Poland. It also indirectly suggests that the Hybrid New Keynesian Phillips Curve, putting emphasis on the role of economic slack in determining inflation, can be an adequate

<sup>&</sup>lt;sup>9</sup> E.g. IMF (2014), p. 14.

<sup>&</sup>lt;sup>10</sup> In the period after the collapse of Lehman Brothers correlation of CPI inflation and DVI is even larger – Pearson and Spearman correlation coefficients equal, respectively: -0.78 and -0.83.

<sup>&</sup>lt;sup>11</sup> According to Kumar *et al.* (2003), minimal deflation risk appear when DVI is smaller than 0.2; small deflation risk – if it is between 0.2 and 0.3, moderate – for DVI between 0.3 and 0.5, while high – for DVI above 0.5.

theoretical concept in explaining recent price developments. In addition, it considers inflation expectations that are not used in calculation of the Deflation Vulnerability Index.

With the diversity of variables used in the estimation of the HNKPC models, in each of the sample periods under consideration there are 120 equations estimated – half of them in terms of the CPI inflation and another half of them in terms of core inflation. Detailed estimation results are presented in the Annex (Table 3, Table 4). Summarising them it should be noted first that in general the theoretical specification of the HNKPC is supported empirically. In a dominant part of estimated equations both past inflation and inflation expectations are needed to explain current inflation. Taking into account the full sample period (2003-2015), past inflation is statistically insignificant only in 20% of models estimated in terms of CPI inflation and in 13% of models estimated in terms of core inflation, respective shares are 45% and 8%. It would suggests that recently CPI inflation has become more persistent, which does not apply in the case of core inflation. We will analyse this issue in the final part of this section, comparing estimated coefficients in both sample periods. Here we can conclude that the hybrid version of the NKPC seems more empirically relevant in Poland than the traditional NKPC. It is in line with the results for European economies reported in the literature.<sup>12</sup>

Analysing estimation results we observe that the problems with incorrect signs of different coefficients or statistical insignificance of explanatory variables are not very frequent (Table 2). The share of HNKPC models that display inconsistencies of this kind amounts approximately to 28% in the full sample and to 17% in the shorter sample period. This share is larger in the case of core inflation than CPI inflation. Insignificant output gap while explaining core inflation or insignificant foreign inflation constitute the major sources of these problems.

# [Table 2 here]

The results of the Hansen *J*-test show that in the case of all the estimated models the null hypothesis of valid overidentifying restrictions cannot be rejected.

Dynamic homogeneity property, making the Phillips curve vertical in the long run, is displayed more often in the short sample period than in the long one and more frequently in the case of CPI inflation than core inflation. Using the sample period 2003-2012 approximately 78% of estimated equations specified in terms of CPI inflation compared to 32% of those specified in terms of core inflation met dynamic homogeneity condition. For the full sample period, 2003-2015, respective numbers equal 80% and 12%. The fact that Phillips curves specified in terms of CPI inflation are vertical in the long run more frequently than those specified in terms of core inflation can be explained with the fact that empirical proxies of inflation expectations used in this study are not consistent with core inflation – both survey-based measures of inflation expectations as well as the NBP inflation target refer to headline inflation, not to core inflation.

Detailed analysis of estimated HNKPC models conducted in the subsequent part of this section takes into consideration only those specifications that do not display inconsistencies described in Table 2. We aim at assessing: first, what combination of proxies for inflation expectations, economic slack and imported inflation guarantee the best statistical fit of the estimated HNKPC; second, which specifications are the most successful in modelling the recent disinflation; third, what changes in estimated coefficients occur during the recent disinflation period.

<sup>&</sup>lt;sup>12</sup> E.g. Paloviita (2008), using pooled European data, shows that the purely forward-looking NKPC is clearly outperformed by the New Classical and Hybrid New Keynesian Phillips curves.

Taking into account the results based on the full sample period (2003-2015) we observe that Phillips curves estimated in terms of core inflation display lower root mean squared errors, RMSE (0.80), than Phillips curves estimated with CPI inflation as the explanatory variable (1.42). The same applies to analogous measures of errors calculated for the period of recent disinflation (2012-2015) which equal 1.42 and 0.66, respectively.

The selection of the price index and particular proxies for determinants of inflation in the Phillips curve have a significant influence on statistical fit of estimated models, especially those, in which headline inflation is the explanatory variable. Figure 5 presents errors of the estimation (differences between fitted and actual values) in the form of Root Mean Squared Errors (RMSE) – both for the whole sample used in the estimation (2003-2015) and during the recent disinflation (2012-2015). We can observe that minimal RMSE corresponds to models, in which survey-based measures of inflation expectations of enterprises are used. This conclusion is consistent with previous findings, based on the small structural New Keynesian (NK) model, showing that enterprises' inflation expectations are the most relevant from the macroeconomic perspective and used in the NK model improve significantly its forecasting accuracy (Łyziak, 2016). In the present results there is only one exception from this observation, i.e. analysing errors in the recent period (2012-2015) of the Phillips curve estimated in terms of core inflation. In this case using survey-based measures of financial analysts' inflation expectations minimizes the forecasting errors during the disinflation period, however models with enterprises' inflation expectations produce only slightly less favourable outcomes.

The best-performing measure of the economic slack is given by the Alichi *et al.* (2009) transformed version of the HP-filter output gap, that captures non-linear effects of the excess demand on inflation in the periods, when the output gap is positive. It suggests that the Phillips curve in Poland displays some asymmetry and that prices are more responsive to the output gap when it is highly positive. It corresponds to findings by Sznajderska (2014), who shows stronger responses of quarter on quarter CPI inflation to output gap when it is positive. However, it should be noted that the differences in statistical fit between HNKPC models using standard version of the HP-filter output gap and the measure proposed by Alichi *et al.* (2009) are very small, especially in the case of models, in which core inflation is explanatory variable.

Finally, it seems that both during the whole sample period and during the recent disinflation the real exchange rate gap is a better proxy for foreign component of domestic CPI and core inflation than the rate of growth of import prices.

# [Figure 5 here]

The above exercise was based on the HNKPC models estimated on the full sample. However, from the empirical point of view it is more relevant to assess out-of-sample properties of those models. To do this we estimate Phillips curves on the shorter sample period, that finishes before the beginning of the recent disinflation. Then we generate forecasts of inflation for the disinflation period (2012-2015) and assess out-of-sample forecasting properties of different Phillips curves.

Paths of inflation forecasts generated on the basis of HNKPC models estimated on the sample 2003-2011 (Figure 6, Figure 7) suggest that those models do not replicate adequately the recent disinflation period, especially in the case of models explaining CPI inflation. Firstly, even if those models seem to anticipate fall in CPI inflation, they are not able to predict the scale of deflation in 2015 – all the CPI forecasts remain above the actual CPI inflation in 2015. Secondly, in the case of core inflation, paths of its forecasts surround the actual figures – there are some specifications that reflect the actual developments of core inflation and some that predict even deeper deflation. However, majority of

forecasts is above the actual core inflation. Thirdly, independently of the inflation measure used a large number of specifications predict increase of inflation in the most recent period (i.e. in 2015), while actual price developments are clearly against this prediction.

# [Figure 6 here]

# [Figure 7 here]

What is the model specification that makes the paths of inflation forecasts closest to actual figures? Analysis of Root Mean Squared Errors (RMSE) of inflation forecasts confirms that both in the case of headline and core inflation this specification should use asymmetrical measure of the HP-filter output gap and the real exchange rate gap. It should be underlined that the deviation of real GDP growth rate from its mean represents another proxy for the economic slack improving inflation forecasts. As far as the measure of inflation expectations is concerned, the models that generate relatively accurate CPI inflation forecasts are those that use enterprises' inflation expectations, while in the case of core inflation forecasts consumer inflation expectations seem more adequate.

Limited ability of the Phillips curve models to predict the recent disinflation leads to the question to what extent the estimated coefficients are different between the models estimated on the full sample (2003-2015) and on the short sample (2003-2011). The results of such inspection depend on the measure of inflation used as explanatory variable.

Analysing directly estimated, short-run coefficients (Figure 9, Figure 10) we observe that in the case of HNKPC models specified in terms of CPI inflation in a dominant part of models inflation persistence becomes larger in the longer sample, covering the recent disinflation. At the same time the impact of other factors, i.e. inflation expectations, economic slack and foreign inflation, is reduced. The results based on core inflation models are more mixed. Majority of them suggest that inflation persistence and the role of inflation expectations have been reduced recently, similarly as the impact of the economic slack on price developments. All at once the impact of foreign inflation on the domestic one has become stronger. However, in the case of each of those coefficients there are also models indicating opposite changes.

# [Figure 9 here]

# [Figure 10 here]

Analysing long-run coefficients (Figure 11, Figure 12) it can be noted that independently of the measure of inflation, the role of inflation expectations has been reduced in the recent period. It is due to the fact that short-term inflation expectations of consumers, enterprises and financial sector analysts, similarly as the remaining proxies for inflation expectations, have been remaining positive – although reduced to historically low levels – despite negative inflation rates. A dominant part of CPI inflation models indicate steepening of the Phillips curve and increased role of foreign inflation in determining domestic price changes, while in the case of core inflation models we observe rather a reduced impact of economic slack and foreign price changes on domestic inflation.

# [Figure 11 here]

# [Figure 12 here]

Being aware of the fact that changes in the coefficients of HNKPC models estimated in terms of headline inflation can be biased due to the fact that this measure of inflation has been strongly

influenced by food and energy prices in the recent period, it seems that analysing stability of the Phillips curve we should rely rather on core inflation models. In addition, conclusions based on those models are comparable with results of similar tests performed using euro area data that are based also on similar measures of core inflation. From this perspective our analysis suggests some flattening of the Phillips curve in recent years as well as a smaller impact of inflation expectations on actual inflation. Flattening of the Phillips curve can be explained with higher openness of the Polish economy, making foreign demand an important determinant of domestic price developments.

Summing up, it seems that the recent disinflation and a prolonged period of deflation in the Polish economy resulted from a combination of global and domestic factors. The HNKPC seems a useful concept capable to explain recent price developments, especially in the case of core inflation. Our analysis suggest that to fit the actual data survey-based measures of enterprises inflation expectations should be used, however, in some tests consumer inflation expectations perform even better than enterprises' expectations. In addition, capturing asymmetric effects of output gap on inflation – stronger when the output gap is positive – improves statistical fit of HNKPC models.

On the other hand, we show that the Phillips curve relationship has not been stable recently. In particular, it seems that core inflation has become less sensitive to economic slack and to inflation expectations.

# 5. Conclusions

The prolonged period of deflation in Poland was not expected, however, it does not seem entirely puzzling. First, standard factors signalling deflation risks, embodied in the Deflation Vulnerability Index – especially those related to inflation performance, economic activity and credit and monetary aggregates – seem informative in the context of Polish deflation. Second, the concept of the Hybrid New Keynesian Phillips Curve seems useful in analysing price developments in Poland, however, the degree of this usefulness is conditional on proxies for explanatory variables being applied. In line with previous studies, based both on Polish and external experiences, survey-based measures of inflation expectations – particularly enterprises' inflation expectations – seem an important factor needed to understand recent price developments. At the same to adequately reflect cyclical component of inflation one should take into account either the transformed output gap measure, making inflation more responsive to output gap when it is highly positive, or the growth rate of real GDP relative to its mean.

Analysing stability of the Phillips curve we find signs of its flattening in recent years. It applies to the models estimated in terms of core inflation, while CPI inflation models suggest rather a steepening of the Phillips curve. Both types of models agree on the weakening of the link between inflation expectations and actual inflation.

The Phillips curve in Poland is alive. We can use it to explain past inflationary performance and to predict its changes, at least to some extent.

Notes: Table presents GMM estimates of the HNKPC models. The sample period is 2003Q1-2015Q3. The set of instruments contains predetermined variables, i.e. three lags of the measures of inflation, economic slack and imported inflation used in each of the specifications.

Source: own calculations.

Notes: Table presents GMM estimates of the HNKPC models. The sample period is 2003Q1-2015Q3. The set of instruments contains predetermined variables, i.e. three lags of the measures of inflation, economic slack and imported inflation used in each of the specifications.

Source: own calculations.
